WFC3: Spectroscopy and Operational Enhancements

John W. MacKenty¹, H. Bushouse¹, R. Gililand¹, B. Hilbert¹, L. Petro¹, N. Pirzkal¹, A. Rajan¹, WFC3Team (¹STScI)

**WFC3 Slit-less Spectroscopy (GRISMs)**

- WFC3 provides low resolution slit-less spectroscopy in the low background ultraviolet and near infrared
- UVIS 0280 Grism \(\rightarrow \lambda / \delta \lambda \approx 70\) over 190 - 450 nm (with some response to \(<180\)nm)
- IR Grisms have excellent primary order energy concentration and out of band rejection.

**CCD Charge Injection and CTE Mitigation**

- WFC3 was installed during solar min thus radiation damage to the CCDs is 2-3 times that seen in the first years of ACS (2002-2004)
- The WFC3 e2V CCDs have a charge injection gate that permits ~17,000 electrons to be placed into every Nth row
- With N=10, this appears to restore CTE to pre-flight levels
- Injected row has readnoise \(~20\)e- but returns to 4-5e- in rest of rows
- Charge Injection will become an option for WFC3/UVIS in Cycle 19

**Spatial Scans for Enhanced S/N WFC3 Spectroscopy**

- STScI and the HST Project are developing a scanning capability that allows the light from astronomical objects to be trailed across the WFC3 detectors in a predictable and repeatable manner during exposures.
- This, if it works as expected, will enable significantly increased S/N observations – especially for infrared spectroscopy of bright sources
  - The default mode of operation will be to move a user defined distance in the cross-dispersion direction.
  - Rates up to 1 arc second per second will be supported in Cycle 19 (higher rates may become possible in future cycles).
  - Testing is planned for Feb-April 2011 and the TAC will be informed of the outcome.
  - Modest overheads combined with the accurate timing information inherent in the MULTIACCUM readouts of the IR detector should make this a powerful capability for infrared spectroscopy of bright time variable sources.
- More details are available in the WFC3 STAN at www.stsci.edu/hst/wfc3/documents/newsletters/STAN_01_06_2011

**Subarray Improvements**

- Improved sub-arrays defined for WFC3 starting in Cycle 18
  - Support some of ACS/NRC parameter space with 1024 x 1024 subarrays in UVIS
  - IR subarrays supported for GRISM
- Cycle 19 Enhancement
  - Image Header limitation of 100 will increase to 304 in Cycle 19
  - Note: each IR readout produces a header

**High Contrast Imaging**

- Cycle 18 calibration program 12354 characterized the profile of the WFC3 Point Spread Function to explore high contrast imaging.
- UVIS F487N, F467N, F680N, F555W, and F775W plus IR F128N
  - Carefully dithered to measure contrast out to \(-2\) arc seconds.
  - WFC3 is capable of detecting sources at \(-1\) arc sec with Amag\(-10\)
  - For UVIS, these calibrations specifically examine the case of a carefully dithered \(12\) inch magnitude star
- Observers considering observations of high contrast sources should examine the 12354 dataset and our analysis.

UVIS: WFC3/IR 2011-03 (Gililand and Rajan)
- IR results to be published soon

---

**Abstract**

The Wide Field Camera 3 was installed into the Hubble Space Telescope in May 2009. Our presentation discusses the performance of the WFC3 near infrared slitless spectroscopy mode, improvements to the definition and use of detector subarrays, and recent experiments aimed at determining the limits of high contrast imaging. We also discuss the implementation status of a new mode to achieve very high signal to noise observations of bright sources in the infrared channel via controlled motion of the telescope. This offers the potential for high S/N photometry and spectroscopy of very bright targets with excellent time resolution.
