

Results from the Outer Planet Atmospheres Legacy (OPAL) Program

Amy Simon

NASA Goddard Space Flight Center

Goals of OPAL

Yearly global maps of each of the outer planets

- Started with Uranus in 2014, and Jupiter and Neptune in 2015
- Saturn starting in 2018 (after Cassini ends in 2017)

Study trends in zonal winds, cloud activity, color, cloud height

- Other unexpected activity
- Not meant to supplant other focused science programs

All maps made available to science community for other studies

- First HLSP release coincides with first manuscript submission for that planet, no delay in subsequent Cycles

Outer Planet Atmospheres Legacy (OPAL)

Introduction

OPAL is a project to obtain long time baseline observations of the outer planets in order to understand their atmospheric dynamics and evolution as gas giants. The yearly observations from OPAL throughout the remainder of Hubble's operation will provide a legacy of time-domain images for use by planetary scientists. The project will ultimately observe all of the giant planets in the solar system (Jupiter, Saturn, Uranus, and Neptune) in a wide range of filters. The images are processed using an ellipsoid limb-fitting technique, with an additional fringe correction applied to the narrow-band filters only (e.g., FQ889N for Jupiter 2014-2015), which amounts to a few percent correction. Mosaics are created for each observed filter in a projection that spans 360 degrees of longitude. See the README files (on disk or in the tables below) for additional details on the data processing. The mosaics from each filter (in FITS format), as well as previews (in TIF format) are provided.

Projections of two rotations from a given Cycle for Jupiter, Uranus, and Neptune. Watch how cloud features change between rotations.

Description of Data Products

Each file name begins with the same prefix: "hisp_opal_hst_wfc3-uvis_". The name of the planet is the next part of the filename. Each rotation/epoch is differentiated by a calendar year and a letter, e.g., "jupiter-2015a" is the first rotation of Jupiter from Cycle 22, "jupiter-2015b" is the second rotation from Cycle 22, etc. Keep in mind that HST cycles span two calendar years, since they start in Oct. and run through Sep. of the following year. The next part of the filename includes the HST filter for that mosaic/preview image, followed by a version number and the file extension. File extensions are:

1. `_globalmap.fits` = Mosaic (projection) for the given filter.
2. `_globalmap-medium.tif` = Preview image (width x height ~ 900 x 450 px, varies by target).
3. `_globalmap-small.tif` = Preview image (width x height ~ 450 x 225 px, varies by target).
4. `_globalmap.tif` = Preview image (size varies by target).

Data Access

You can retrieve the images and previews from the table below, or directly at [this URL](#).

Jupiter: January 2015, February 2016

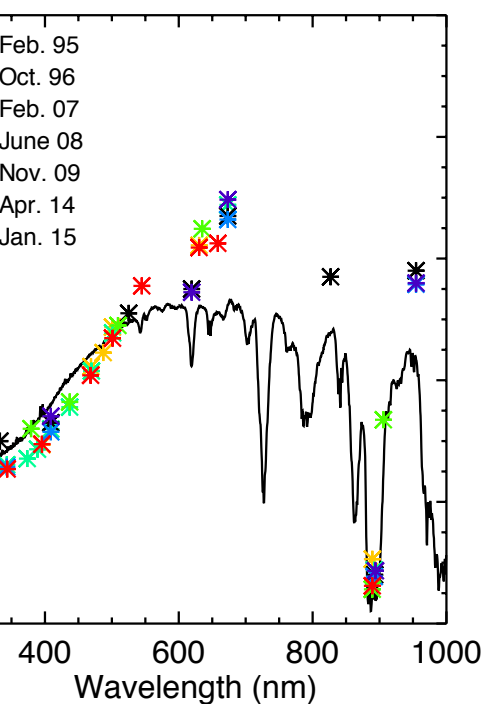

Jupiter: Results

Simon, Wong and Orton, *ApJ* 812, 55

NEB Color Evolution

GRS Color Evolution

Great Red Spot remains intense orange color, still shrinking; internal structure has a reduced core and spiral cloud patterns

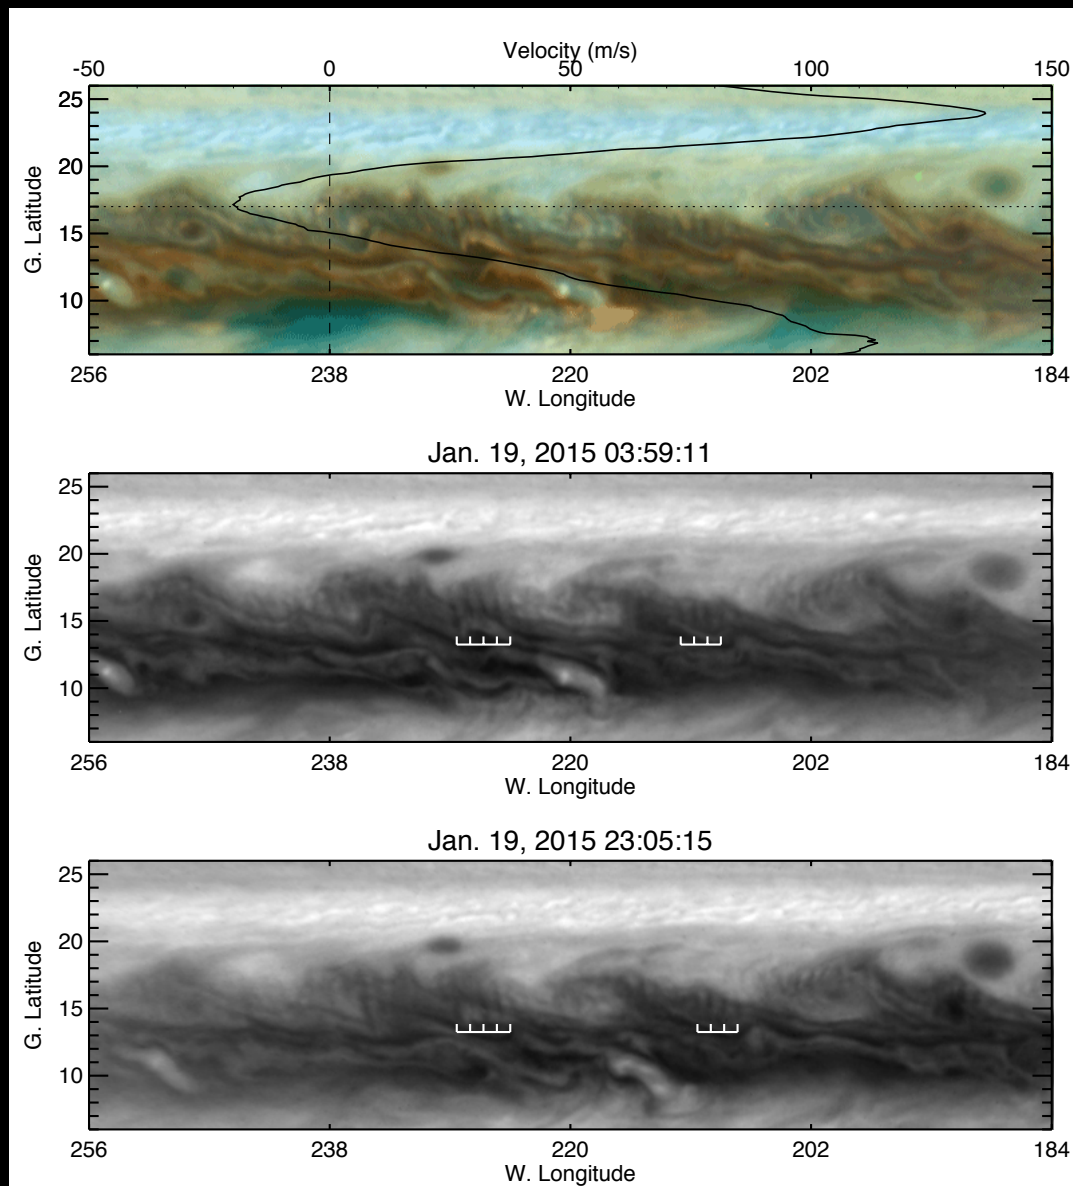

Jupiter: Results

baroclinic wave spotted
never before seen by Hubble
analogous to mid-latitude cyclone
formation on Earth

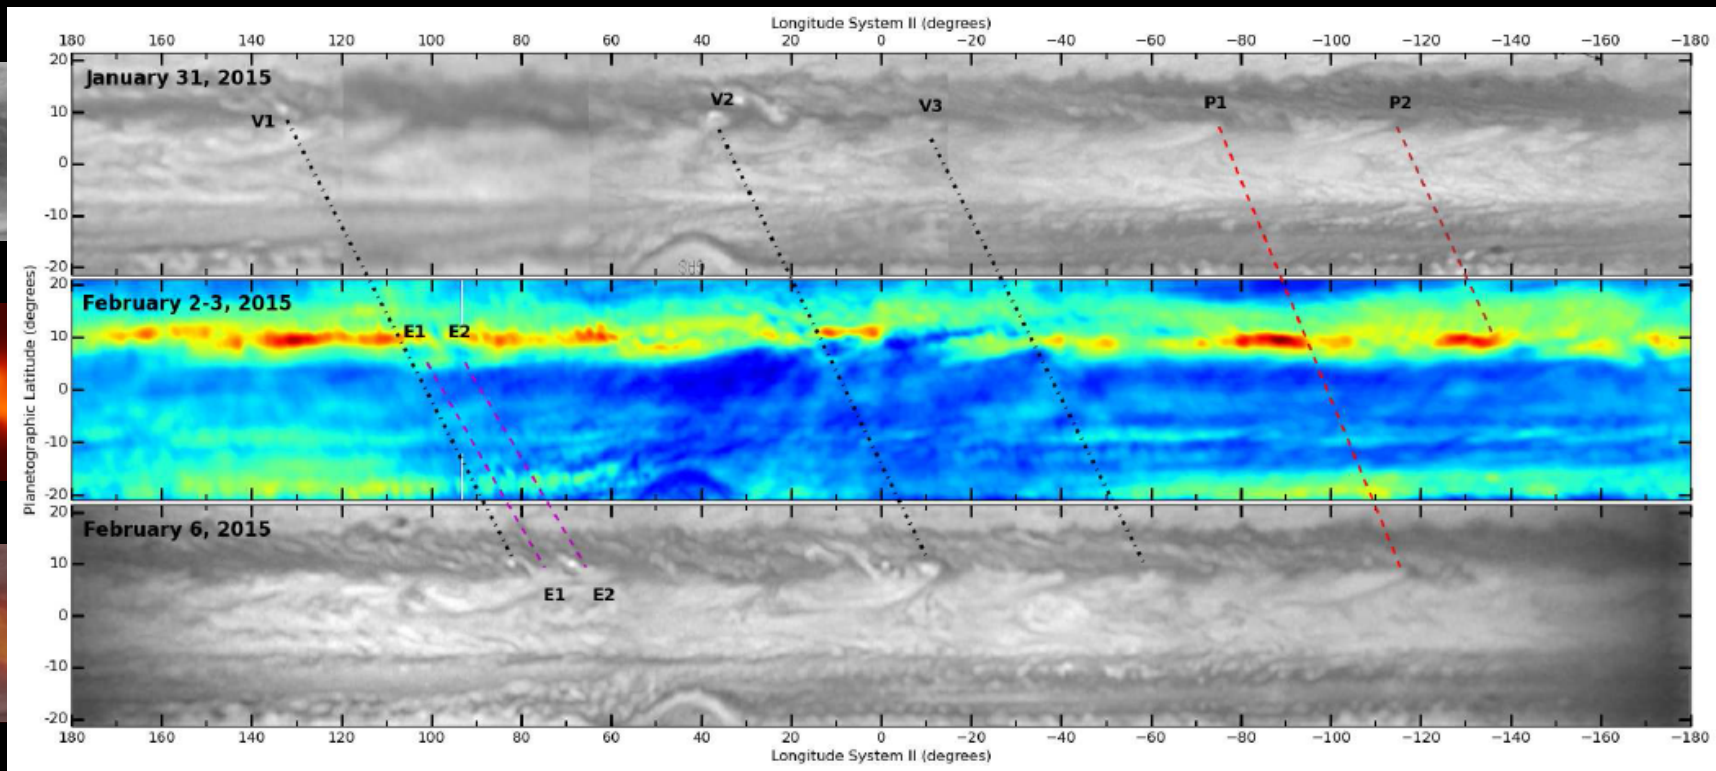

on, Wong and Orton, *ApJ* 812, 55

Jupiter: Ongoing

g Visible, IR and Radio data!

Cosentino et al., submitted

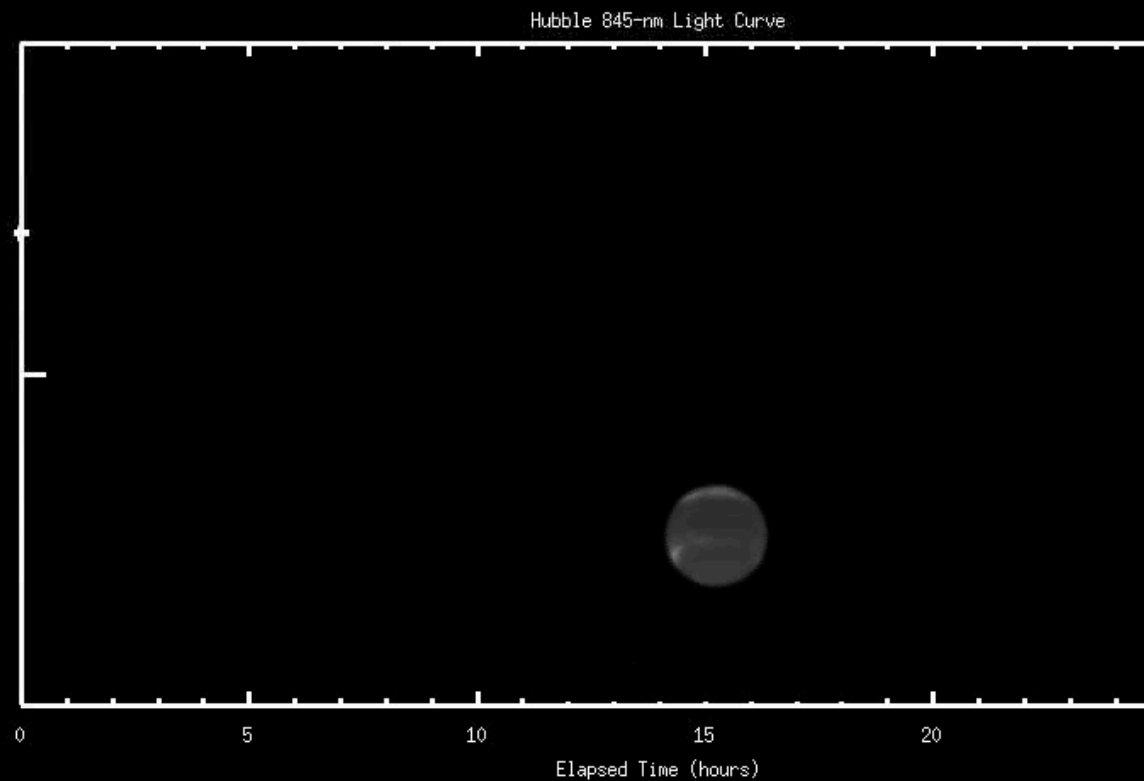

Neptune: November 2015 and Oct. 2016

Neptune: Results

place Kepler K2 light curve into context
term variability (from clouds) important for
standing brown dwarf light curves

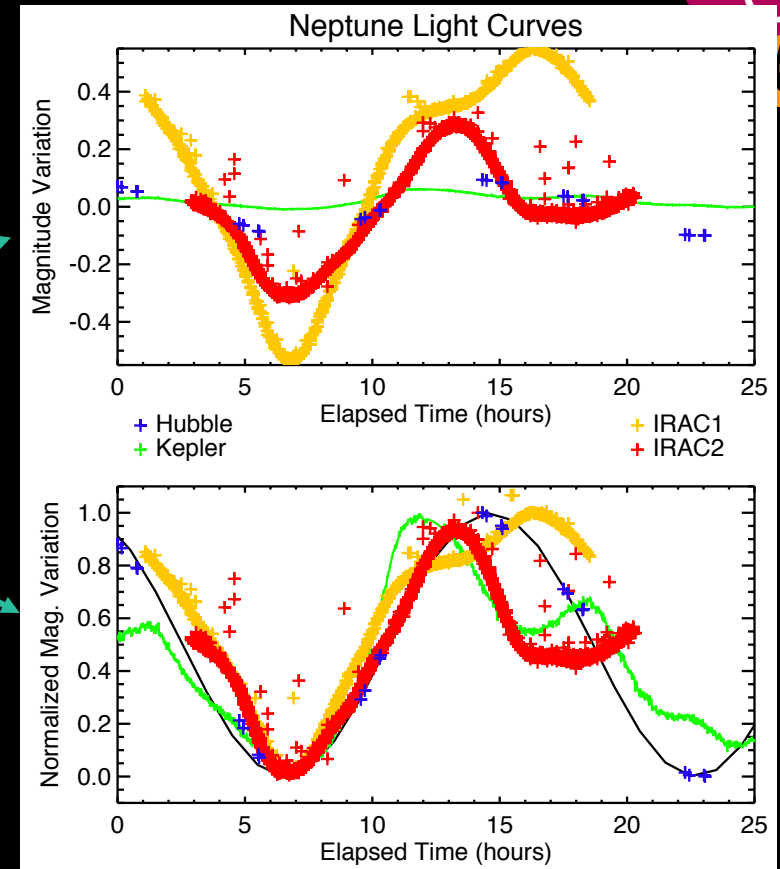

Simon et al ApJ 817, 162

Neptune: Results

Neptune was observed in the infrared by Spitzer/IRAC in Feb 2006 and compared with visible data from Kepler and Hubble. Amplitude of brightness variations are caused by wavelength sensitivity; only the very highest clouds are seen at visible wavelengths.

Neptune's rotation period (black line) dominates the light curves, but deviations indicate rapid evolution of large cloud features.

2016 Hubble 2D Global Map Projection (red wavelength)
North Pole not visible from Earth

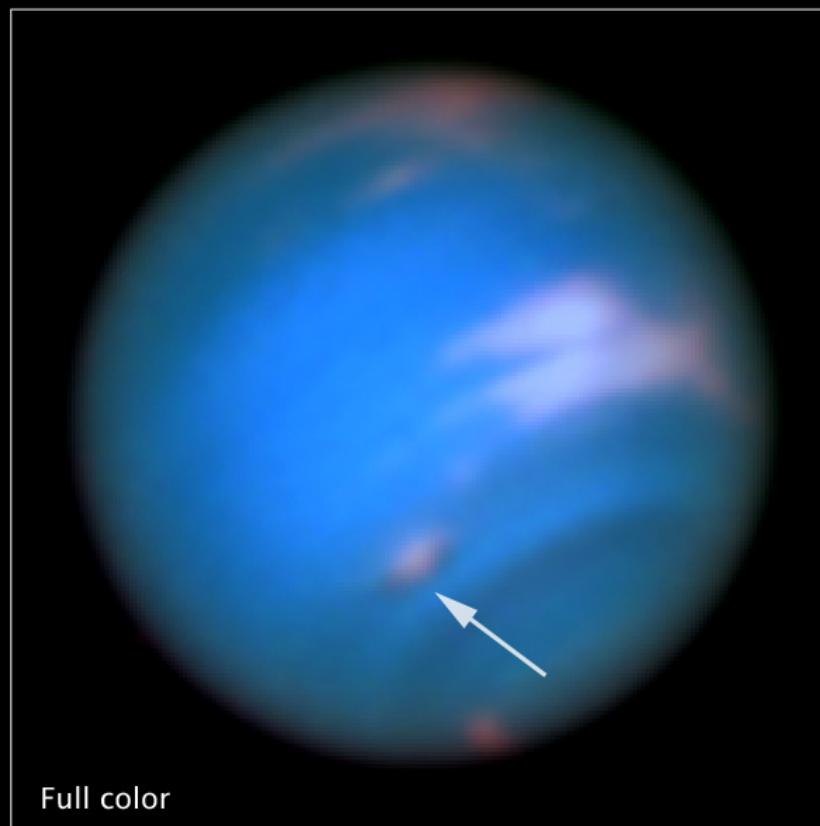

Imaging provides ultimate ground-truth, important for interpreting variability in light curves from unresolved stellar objects and exoplanets

Neptune: Ongoing

The new Great Dark Spot

Dark Spot on Neptune ■ May 16, 2016 ■ *Hubble Space Telescope* ■ WFC3/

Full color

Blue light

NASA, ESA, and M.H. Wong (UC Berkeley) ■ STScI-PRC16-22a

Jupiter: Nov. 2014, Sept. 2015, 2016

Jupiter: Results

actually had quite a bit of cloud activity, less in 2015
combined with ground-based SINFONI and IRTF data to
reveal cloud structure
not over such a broad wavelength range!
deep cloud, methane ice cloud, and hazes

Janus: Ongoing

New 2016 images show more distinct clouds.

Summary

OPAL has already been scientifically productive

- 3 published papers, several more submitted or in prep

Formed a number of new collaborations and projects beyond our proposed science

Allows us to plan for simultaneous observations with other facilities

Value of multi-wavelength observations has been demonstrated (IRTF/VLT/VLA/Keck/others)

Supports other missions (an upcoming Juno periapse will coincide with next Jupiter observations)
