50 Total Orbits Used

## **ABSTRACT**

We propose an ACS/HRC snapshot survey of 50 post-AGB sources, objects which have evolved from the AGB but may or may not become planetary nebulae (PNe). This survey will complement existing HST images of proto-planetary nebulae (PPNe) and PNe in addressing circumstellar envelope morphology as a function of: 1) the progenitor star mass; 2) the chemical composition; and 3) evolutionary stage. We will connect the observed diversity of nebular shapes with the main physical and chemical conditions characterizing post-AGB objects, to identify the mechanism that breaks the symmetry of AGB mass loss. To our knowledge, no previous HST projects have been specifically designed to address this issue. From our database of 360 post-AGB candidates, we have selected approximately 50 targets, none of which have been or are being observed with HST, to sample different central star masses, chemical compositions, and evolutionary stages, uniformly across the sky. These new data will also provide important constraints to a quantitative analysis of Spitzer Space Telescope (SST) observations planned for a similar sample of objects. We will model the HST images and SST spectra using our axisymmetric dust code 2-Dust, to derive dust density distributions, pole to equator density ratios, dust shell masses, inclination angles as well as dust composition.

## **OBSERVING DESCRIPTION**

Our snapshot survey of post-AGB objects has the primary goal of imaging the circumstellar material to constrain the geometry of the AGB mass loss. Circumstellar material is known to exist around these post-AGB stars from the infrared excess observed. Our sample includes a number of optically bright sources, for which high contrast imaging will be required to see the expected low surface brightness nebulae. A smaller fraction of optically fainter sources will require deep imaging.

This snapshot program of 50 targets has been designed for ~20-30 minute orbit lengths, where the typical orbit layout includes exposures with the ACS/HRC camera in F606W and F814W. Three depths of exposure are taken, with the shortest exposure (~0.1 seconds), used to obtain an unsaturated image of the target, a deeper exposure (~10 seconds), for a reasonable exposure on nebulosity, and a very deep exposure (~100 seconds), for a reasonable exposure on faint nebulosity. For the fainter targets, a simple deep exposure in F814W will be obtained.
