123 Total Orbits Used

ABSTRACT

Star formation is a fundamental astrophysical process; it controls phenomena ranging from the evolution of galaxies and nucleosynthesis to the origins of planetary systems and abodes for life. The WFC3, optimized at both UV and IR wavelengths and equipped with an extensive array of narrow-band filters, brings unique capabilities to this area of study. The WFC3 Scientific Oversight Committee (SOC) proposes an integrated program on star formation in the nearby universe which will fully exploit these new abilities. Our targets range from the well-resolved R136 in 30 Dor in the LMC (the nearest super star cluster) and M82 (the nearest starbursting galaxy) to about half a dozen other nearby galaxies that sample a wide range of star-formation rates and environments. Our program consists of broad-band multiwavelength imaging over the entire range from the

UV to the near-IR, aimed at studying the ages and metallicities of stellar populations, revealing young stars that are still hidden by dust at optical wavelengths, and showing the integrated properties of star clusters. Narrow-band imaging of the same environments will allow us to measure star-formation rates, gas pressure, chemical abundances, extinction, and shock morphologies. The primary scientific issues to be addressed are: (1) What triggers star formation? (2) How do the properties of star-forming regions vary among different types of galaxies and environments of different gas densities and compositions? (3) How do these different environments affect the history of star formation? (4) Is the stellar initial mass function universal or determined by local conditions?

OBSERVING DESCRIPTION

The primary goal of this proposal is to observe star formation in a wide range of environments in the local universe in order to determine how star formation is triggered, how it is regulated through feedback, and the degree to which it is universal. These different environments dictate the need for a range in observing strategies. The targets are therefore broken into the following four groups: 1) S0 galaxies in the Virgo Cluster, 2) nearby "quiescent" galaxies, 3) nearby "starbursting" galaxies, 4) and local young star clusters. While the observing strategies vary considerably for these four groups, we provide a degree of commonality by observing with the same seven broad-band filters (F225W, F336W, F438W, F555W, F814W, F110W, F160W), plus a narrow-band H α filter, whenever feasible.

The exposure times are designed to reach S/N=5 for a 10 Myr cluster with $M_v=-4$ and a typical extinction of $A_v=0.5$ in most of the bands. In a few cases (such as the F160W observations in more distant galaxies) we are not able to reach this design goal, but come within about 1 magnitude. The narrow band exposure times are scaled to previous HST observations of a metal-poor or a metal-rich galaxy.

In order to improve resolution, eliminate hot pixels, etc we use standard dithering strategies. Our default is a 4point dither box, but we often have to use a 3-pt dither line due to buffer dump and parallel exposure constraints.

Proposal 11360 - Visit 11 - Star Formation in Nearby Galaxies
