ABSTRACT

The first generations of galaxies were assembled around redshifts $z \sim 7-10+$, just 500-800 Myr after recombination, in the heart of the reionization of the universe. We know very little about galaxies in this period. Despite great effort with HST and other telescopes, less than ~ 15 galaxies have been reliably detected so far at $z > 7$, contrasting with the ~ 1000 galaxies detected to date at $z \sim 6$, just 200-400 Myr later, near the end of the reionization epoch. WFC3 IR can dramatically change this situation, enabling derivation of the galaxy luminosity function and its shape at $z \sim 7-8$ to well below L^* , measurement of the UV luminosity density at $z \sim 7-8$ and $z \sim 8-9$, and estimates of the contribution of galaxies to reionization at these epochs, as well as characterization of their properties (sizes, structure, colors). A quantitative leap in our understanding of early galaxies, and the timescales of their buildup, requires a total sample of ~ 100 galaxies at $z \sim 7-8$ to ~ 29 AB mag. We can achieve this with 192 WFC3 IR orbits on three disjoint fields (minimizing cosmic variance): the HUDF and the two nearby deep fields of the HUDF05. Our program uses three WFC3 IR filters, and leverages over 600 orbits of existing ACS data, to identify, with low contamination, a large sample of over 100 objects at $z \sim 7-8$, a very useful sample of ~ 23 at $z \sim 8-9$, and limits at $z \sim 10$. By careful placement of the WFC3 IR and parallel ACS pointings, we also enhance the optical ACS imaging on the HUDF and a HUDF05 field. We stress (1) the need to go deep, which is paramount to define L^* , the shape, and the slope α of the luminosity function (LF) at these high redshifts; and (2) the far superior performance of our strategy, compared with the use of strong lensing clusters, in detecting significant samples of faint $z \sim 7-8$ galaxies to derive their luminosity function and UV ionizing flux. Our recent $z \sim 7.4$ NICMOS results show that wide-area IR surveys, even of GOODS-like depth, simply do not reach faint enough at $z \sim 7-9$ to meet the LF and UV flux objectives. In the spirit of the HDF and the HUDF, we will waive any proprietary period, and will also deliver the reduced data to STScI. The proposed data will provide a Legacy resource of great value for a wide range of archival science investigations of galaxies at redshifts $z \sim 2-9$. The data are likely to remain the deepest IR/optical images until JWST is launched, and will provide sources for spectroscopic followup by JWST, ALMA and EVLA.

OBSERVING DESCRIPTION

To establish the properties of typical galaxies at $z \gtrsim 7$, we must go faint enough to measure sub- L^* galaxies. A very thorough and careful evaluation of different filter and orbit combinations independently by two team members suggests that with 192 WFC3 IR orbits in three filters we can find large numbers of z-dropout sources at $z \sim 7-8$ and Y-dropouts at $z \sim 8-9$. We will search for $z \sim 10$ J-dropouts, but expect only very small numbers. Our deep WFC3 IR fields would be positioned over the HUDF, HUDF05-1, and HUDF05-2 to take advantage of the superb depth of their optical and z-band data. We selected F105W, F125W and F160W for our WFC3 IR filters to provide for separation between the central wavelengths of the filters and maximal leverage in color. The F160W filter offered greater colour leverage over the F140W that more than offset the difference in efficiency. Use of the F160W filter also improved the probability that we would find some $z \sim 10$ galaxies.

Our lower redshift $z \sim 4-6$ results were extrapolated to estimate L^* at $z \gtrsim 7$. We estimate that $m^* \sim 27.1$ at $z \sim 7.4$ and $m^* \sim 27.7$ at $z \sim 8.3$. We must probe deeper than this by ~ 2 mag (to 29 AB mag) if we are to establish the luminosity density contributions from "typical" sub- L^* galaxies, the volume density, and the overall shape of the LF at $z \sim 7.4$. Such depth would also allow us to set constraints on L^* and ϕ^* at $z \sim 8.3$. After considerable testing we established that the best strategy was a deep field on the HUDF (to ~ 29 AB mag), plus two shallower ones on the HUDF05 fields (to 28.6 AB mag). This nicely matches the depth of available optical data. To reach 28.6 AB mag with our selection, we found we needed ~ 50 orbits split between three filters. The optimal distribution of the ~ 50 orbits within our filter set (F105W, F125W, F160W) was decided upon by running simulations where we calculated the number of dropouts expected to be found for different integration times in each of the three filters. The integration times found to be best are 11 orbits F105W, 18 orbits F125W, and 19 orbits F160W for our shallower two fields and 22 orbits F105W, 36 orbits F125W, and 38 orbits F160W for our deepest field. Our simulations also showed that putting more orbits into a deeper WFC3 IR field on the HUDF improved our constraints on the faint-end slope while lessening cosmic variance at somewhat brighter magnitudes by having two other WFC3 fields. This strategy worked better than one featuring three fields with identical 64-orbit depths.

The ACS parallel observation filters are the same as used in the very successful ACS GOODS and HUDF programs, allowing co-addition with previous data to push current $z \sim 4-6$ dropout selections even deeper than before. To maximize the depth of the ACS optical observations and to make the selection of $z \geq 7$ galaxies even more robust over our three WFC3 fields, the orient requirement on the visits will be set such that the ACS parallel observations land on 2 of our 3 primary WFC3 fields (i.e., either the ACS HUDF or ACS HUDF05-2 fields).

Our dither strategy for the WFC3/IR primary and ACS/WFC parallel observations was devised to include (1) several large ~ 3 arcsec dithers in the +y ACS/WFC direction to effectively step across the ACS gap, (2) smaller 4-point dithers to cope with WFC3/IR's undersampling of the HST PSF and

therefore to improve the resolution of the final data set, and (3) several $\sim 1\text{-}2$ arcsec intermediate-sized $+x/-x$ dithers to maximize the range of different dither positions within our set of observations.
