ABSTRACT

We propose to secure narrow- and broad-band images of compact planetary nebulae (PNe) in the Galactic Disk to study the missing link of the early phases of post-AGB evolution. Ejected AGB envelopes become PNe when the gas is ionized. PNe expand, and, when large enough, can be studied in detail from the ground. In the interim, only the HST capabilities can resolve their size, morphology, and central stars. Our proposed observations will be the basis for a systematic study of the onset of morphology. Dust properties of the proposed targets will be available through approved Spitzer/IRS spectra, and so will the abundances of the alpha-elements. We will be able thus to explore the interconnection of morphology, dust grains, stellar evolution, and populations. The target selection is suitable to explore the nebular and stellar properties across the Galactic Disk, and to set constraints on the Galactic evolutionary models through the analysis of metallicity and population gradients.

OBSERVING DESCRIPTION

The specific goal of this observing program is to obtain images of a large fraction of Galactic PNe with angular diameter $< \sim 4''$ that will also be observed with Spitzer/IRS, excluding those that have already been observed with the HST imaging modes. We will use the WFC3 to obtain monochromatic images with F502N. The high spatial resolution will enable an accurate determination the nebular photometric radius, the morphological type and, with well exposed images, will reveal the presence and physical scale of polar outflows, ansae, outer shells, and halos. The F502N filter is the appropriate match to the selection techniques for these samples, and is free of other nebular emission lines.

We define our final sample by all Galactic PNe not in the Bulge or the Halo, smaller than $\sim 4.0''$ in size, with the further constraint that the surface brightness must be high enough to yield a $S/N > 16$ per pixel in a 30 min exposure in F502N. In practice this latter constraint means nebulae must have $\log F(5007) > -14.7$.

Central stars at 2 kpc will vary in (unreddened) magnitude between $V=16$ to 21, and in temperature from 30,000 K to more than 100,000 K. $E(B-V)$ varies from 0.2 to 3.6 mag, and in distance from 2.0-12 kpc. We will observe each with F200LP and F350LP to identify the ionizing source unambiguously in a (potentially crowded) field, and to measure the UV continuum magnitudes. The intrinsically large variation in brightness and distance, which is not known in advance, force us to bracket our exposure times, nominally between 1 and 10s; this is modified by knowledge of the interstellar extinction, to values not to exceed 240s per UV filter.

We will also obtain an F814W exposure to detect (or exclude the possibility of) a cool companion star, which could be as bright as a G2V ($V=16$ @ 2kpc) and as faint and cool as a Main Sequence M5V star ($V=23$ @2kpc). The nominal continuum exposure times will be 10 s but will be adjusted for the interstellar extinction to as much as 120s.
