136 Total Orbits Used

ABSTRACT

Most galaxies at $z > 1$ with Milky Way stellar masses are actively forming stars at rates 10-100x higher than that of our Milky Way. More surprising was the discovery that most of the star formation resides among giant star-forming clumps. The origin, properties, and evolution of these clumps remain under debate, yet they are vital to our understanding of initial bulge formation, the evolution of early gas-rich disks, and the cold gas accretion history of galaxies. Because these clumps are often visible only in the rest-frame UV, they are easily detected in observed optical images of high redshift galaxies. But at low redshifts ($0.05 < z < 0.25$), resolving star-forming clumps is only possible with HST UV imaging. The number of current identified clumpy galaxies at $0.05 < z < 0.25$ is far too few to measure the evolution in the frequency of clumpy star formation from high redshifts to today. To remedy this deficiency, we propose an UV snapshot survey to image a representative sample of 136 massive star-forming galaxies at $0.05 < z < 0.25$ with the WFC3/UVIS F225W filter to: (1) determine whether any of the local clumpy galaxies are analogs to those seen at high redshift; (2) characterize the nature of these local clumps; and (3) measure the spatial distribution and evolution of star formation (SF) within these clumpy galaxies. HST's access to deep UV imaging at the required high-spatial resolution to detect and resolve local clumps is unique. The high-resolution UV images of our sample will serve as an invaluable legacy dataset for further extragalactic studies for years to come.

OBSERVING DESCRIPTION

Our proposed observations consist of SNAPSHOT imaging of 136 galaxies at $0.05 < z < 0.25$ with the WFC3/UVIS F225W filter. The visit of each galaxy is divided into three 400-second exposures using a three-point dithering pattern with the point spacing of 4.305 arcseconds.
