75 Total Orbits Used

## **ABSTRACT**

We propose WFC3/UVIS snapshot observations of a sample of 75 isolated early type galaxies residing in cosmic voids or extremely low density regions. The primary aim is to use their globular cluster populations to reconstruct their evolutionary history, revealing if, how, and why void ellipticals differ from cluster ellipticals. The galaxies span a range of luminosities, providing a varied sample for comparison with the well-documented globular cluster populations in denser environments. This proposed WFC3 study of isolated early type galaxies breaks new ground by targeting a sample which has thus far received little attention, and, significantly, this will be the first such study with HST.

Characterizing early type galaxies in voids and their GC systems promises to increase our understanding of galaxy formation and evolution of galaxies in general because isolated objects are the best approximation to a control sample that we have for understanding the influence of environment on formation and evolution. Whether these isolated objects turn out to be identical to or distinct from counterparts in other regions of the Universe, they will supply insight into the formation and evolution of all galaxies. Parallel ACS imaging will help to characterize the near field environments of the sample.

## **OBSERVING DESCRIPTION**

With a 33 percent completion rate, our 75 allocated snapshots will net 25 objects, about 2/3 E, 1/3 S0. This will provide a robust sample for meaningful comparison with non-void populations.

The WFC3 primary imaging observations are straightforward. Each target will be observed in the extremely wide WFC3 filters F475X and F600LP. These filters maximize the detection depth while still obtaining excellent blue B+V and red R+I photometric bands to characterize the color distributions of the globular cluster (GC) systems. Each of the targets will be imaged for 2x500s in each

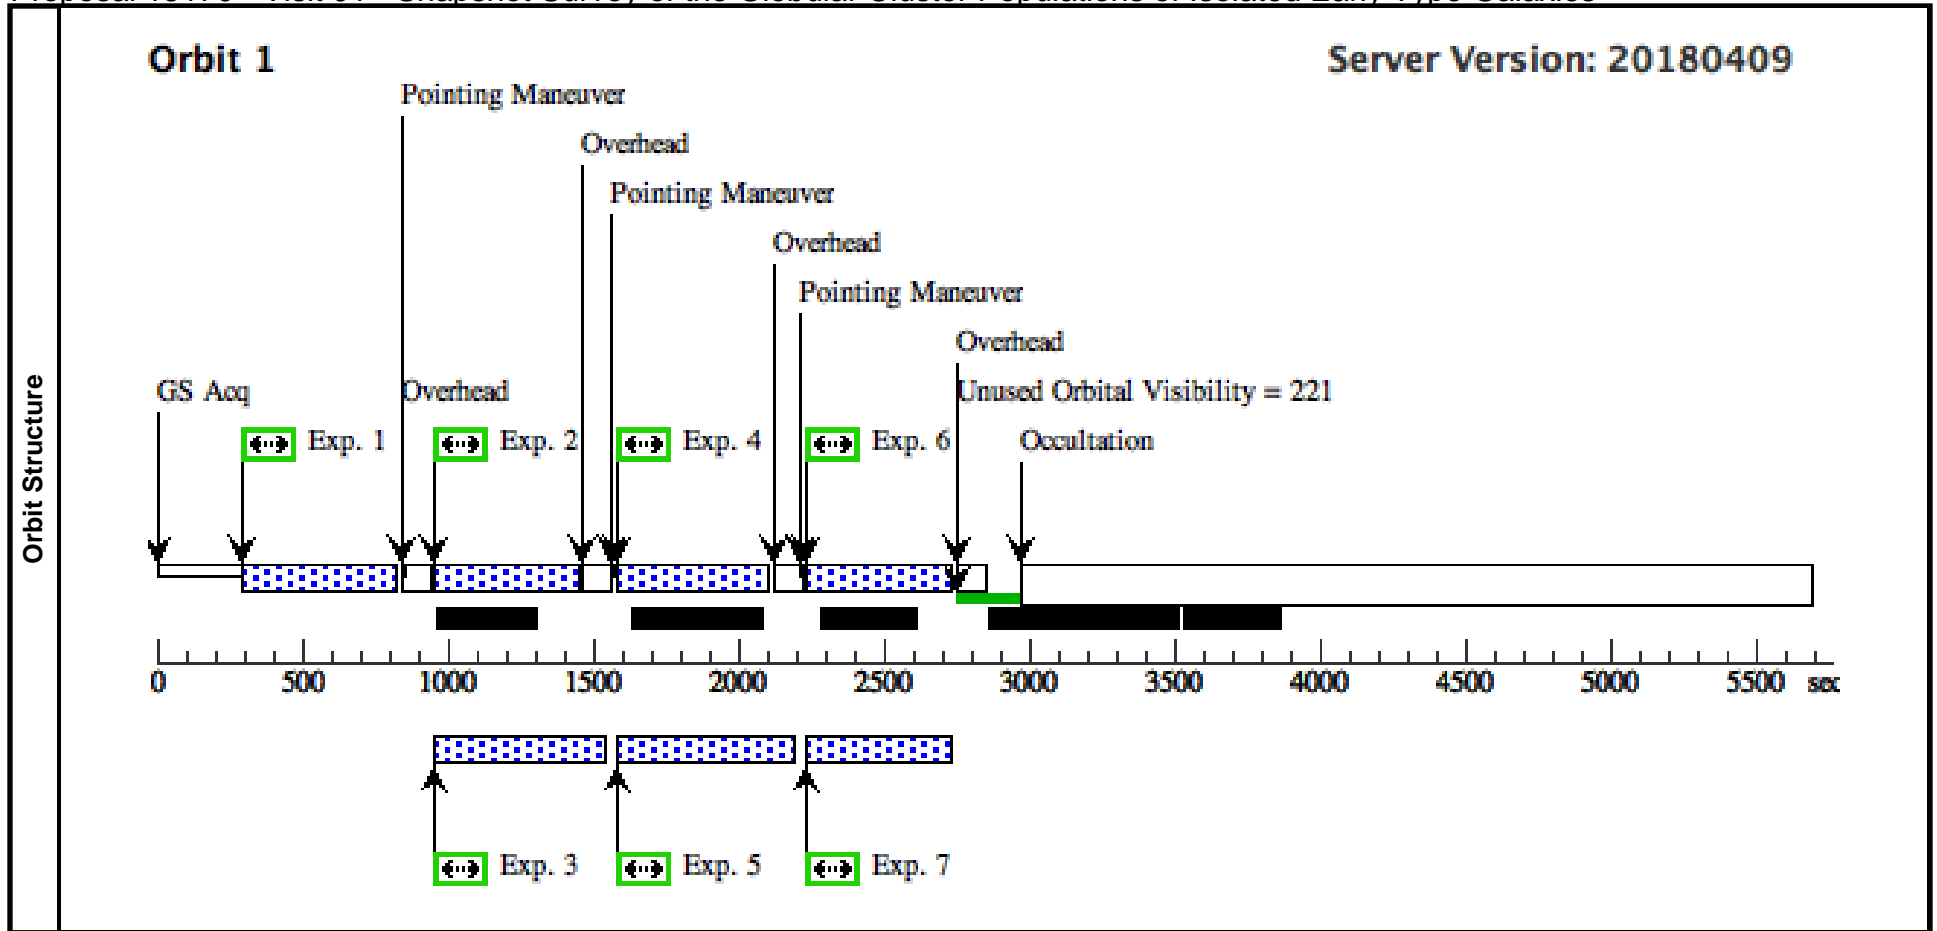

filter, which budgets to about a 45 minute snapshot, and we will employ a four point dither, obtaining the blue exposures on one diagonal and red on the other diagonal of the box pattern. The most distant target is 90 Mpc away, closer than the Coma cluster, and these filters are considerably faster than those used in the Coma Treasury survey (Carter et al. 2005) which successfully measured the GC population at that distance (Peng et al. 2005). The proposed extremely wide WFC3 filter observations will reach significantly deeper down the GC luminosity function.

The ACS parallel imaging parallel will obtain information on the point source colors in the vicinity of the targets. Because of buffer dump timing limitations during the 45 minute snapshot, it is possible to obtain only a single full-detector exposure with ACS, so the these data will be shallower, and still valuable for detecting any far-field component of the cluster population or possible dwarf/UCD companions that have been overlooked in ground-based imaging and spectroscopy to date. We will use the combination of F475W and F814W to approximate both the primary WFC3 imaging and to make these data directly comparable to the Coma Treasury survey data, providing a control and comparison sample.
