ABSTRACT

Low-mass (under 1,000,000 MSun) supermassive black holes (light-weight SMBHs) are critical to solve one of the long-standing problems in modern astrophysics, the origin of SMBHs. Their host galaxies hold important clues to our understanding of galaxy formation and evolution processes: they might have evolved from ancient times in the early Universe without major merger events or intense gas accretion on-to their nuclei and, therefore, represent the relics of primordial galaxy formation. Using optical selection of AGN features and data from X-ray archives, we confirmed 124 light-weight active SMBHs, only 8 of which have available HST images. Here we propose to carry out near-UV/optical imaging of the 116 remaining light-weight SMBH host galaxies using HST WFC3 in the form of a SNAP program, boosting HST-observed light-weight SMBHs by larger factors. This project will yield sizes, luminosities, and stellar populations of a statistically significant sample of hosts, and probe whether the MBH-Mbulge scaling relation holds in the low-mass regime and central low-mass black holes do indeed co-evolve with host galaxy spheroids.

OBSERVING DESCRIPTION

HST high-resolution imaging capabilities are absolutely essential to achieve our goals. Ground based adaptive optics assisted imaging can provide comparable or even higher spatial resolution, however, the broad component of the AO point spread function which contains typically about 50% of energy and usually cannot be directly measured severely hampers the 2D decomposition efficiency. Near-UV images target the central point source, which in principle can be done using a small UV telescope on board the NASA Swift satellite. However, given that our target galaxies have current star formation and have spatial sizes of a few arcsec, Swift-UVOT imaging would have insufficient resolution to isolate the central point source

associated with an AGN to measure its flux.

We propose to use WFC3-UVIS with the F300X, F475W, and F814W filters. We reviewed the strategy successfully used in the past in the HST Cycle 22 proposal 13943 (PI: Reines) and modified it to better suit our needs: (i) the near-UV imaging in the F300X (which goes 3 times as deep as F275W used in prop. 13943 for the same exposure time) is required to estimate the UV continuum from the AGN and also measure star formation activity in the galactic discs of host galaxies; (ii) F814W (Ic) will be the primary filter for the two-dimensional light profile decomposition while optical images are used to estimate structural properties, where dust attenuation is not as important as in the blue bands but the width of the instrumental PSF is still small; (iii) F475W (SDSS g) will be crucial for the analysis of stellar population properties of host galaxies in a combination with F814W. We propose to observe every galaxy in all three filters in one orbit, with the total observing time split equally between the three bands, hence increasing the depth of optical images compared to prop. 13943 by some 25% and keeping the UV depth by choosing a wider filter (F300X) with a higher peak throughput at comparable wavelengths to F275W. We request WFC3 rather than ACS because of NUV capabilities and a 20% finer pixel scale.

We used the WFC3 ETC to estimate the signal-to-noise ratio using best-fitting models of the light profiles of our targets from the Simard et al. (2011) catalog. We estimate that we will reach S/N ratios between 50 and 200 per pixel in the central regions of the IMBH host galaxies where we need to perform a two-dimensional light profile decomposition. We do not have clear predictions for the UV AGN continuum in the proposed targets (GALEX photometry cannot be used because of ubiquitous current or recent star formation). However, from the results of the past observational campaign by Reines et al. available in the HST archive (proposal 13943) the detections appear to be relatively weak, motivating the decision to change the filter to F300X so that even with a slightly shorter integration in the UV we will still go twice as deep, and hence place strong constraints on the AGN SEDs. This proves that with 1 orbit per target split equally in 3 filters we can complete science goals of our program.

To tackle cosmic ray hits efficiently and also fill the chip gap of WFC3/UVIS, we will split each integration into 2 dithered sub-exposures. The first 5 sub-exposures (2*F300X, 2*F475W, 1*F814W) will be 348sec long (the minimum required time to allow for the buffer dump during the subsequent exposure), the 6th exposure will be chosen to fit the available remaining orbital time (from 310sec to 370sec depending on the coordinates of a source). We chose the full detector rather than a sub-raster readout despite somewhat higher overheads in order to increase the legacy value of our dataset. As recommended by the WFC3 instrument handbook, we will use flash to improve the charge transfer efficiency.

Proposal 17177 - Visit 01 - Snapshot survey of host galaxies of active 'light-weight' supermassive black holes
