ABSTRACT

Nearby powerful AGN provide the best way to understand the growth of supermassive black holes (SMBH) and their effect on galaxies. The swift-BAT survey, with its all-sky coverage that is insensitive to obscuration up to Compton-thick levels, provides the largest, most complete sample of local (z<0.1), powerful AGN. These AGN have similar luminosities to the distant AGN typically found in deep, pencil-beam Chandra surveys and are thus a critical nearby template for luminous high-redshift AGN. This program is the first large (N>30) systematic survey using the bluest wide ACS filter (F435W) to accurately trace the nuclear star formation and AGN-related PSF emission at typical scales of 50 pc.

OBSERVING DESCRIPTION

For the sample, we selected all z<0.1 unbeamed AGN, which have reliable measurements of MBH through broad Balmer emission lines or velocity dispersions (639 AGN) which are spread randomly across the sky. We further restricted the sample to have galactic extinction of E(B-V)<0.1, to ensure that high-spatial-resolution, high-S/N imaging can be obtained in relatively short \textit{HST} exposure. We exclude 30 AGN with previous blue imaging (i.e., 435W, 438W, 439W, 450W). The final sample of unobserved AGN then totals 389, of which 199 have existing broadband redder HST imaging (F606W or F814W) enabling studies of integrated colors and color gradients. We will follow the past I-band program of BAT AGN, using a 2-point dither pattern with a 337s at each dither position, for 25 minutes with acquisition. For Type 1-1.9 AGN, we add a short (5s) sub-arrayed exposure (WFC1B-512), as our brightest Sy 1 will saturate in 30s. We split our sample based on sources with D25>50" or with close mergers, placing those at the center WFC, using a 3" dither to cover the central gap. For the smaller sources we place them at WFC1 with a smaller dither to better sample the PSF.
