

# 18037 - Search for massive sub-kpc dual active galactic nuclei in the most luminous quasars

Cycle: 33, Proposal Category: SNAP

(Availability Mode: SUPPORTED)

## INVESTIGATORS

<i>Name</i>	<i>Institution</i>
<b>Ha My Do (PI) (Contact)</b>	<b>University of Southern California</b>
Dr. Kris Pardo (CoI) (CoPI) (Contact)	University of Southern California
Prof. Jenny Emma Greene (CoI)	Princeton University
Dr. Andrew Goulding (CoI)	Princeton University

## VISITS

<i>Visit</i>	<i>Targets used in Visit</i>	<i>Configurations used in Visit</i>	<i>Orbits Used</i>	<i>Last Orbit Planner Run</i>	<i>OP Current with Visit?</i>

## ABSTRACT

Supermassive black hole binaries (SMBHBs) are expected to dominate the nanohertz gravitational wave background (GWB). The large GWB amplitude measured by pulsar timing arrays (PTAs) suggests that there are more binaries than predicted by major merger models. Merging SMBHBs in the local universe correspond to close-separation massive dual AGN progenitors at  $z=0.15-0.9$ . However, we have detected very few sub-kpc dual AGN massive enough to contribute to the GWB in this redshift range. We propose a SNAP with WFC3/UVIS of the 146 most luminous Type-2 AGN selected from SDSS in  $z=0.1-0.4$  to detect the most massive sub-kpc dual AGN predicted by the GWB. Only a WFC3/UVIS SNAP can provide a large enough sample at a high enough resolution for our science goal of characterizing the population of PTA-mass sub-kpc dual AGN. With this data, we can constrain the abundance of sub-kpc duals and test the population of SMBHBs predicted by the measured GWB. Furthermore, this observation would allow us to study the demographics of SMBHBs and their host galaxies to aid future detection efforts.

## OBSERVING DESCRIPTION

We propose the 146 most luminous, and thus most massive AGN that are relevant to the GWB. These Type-2 AGN are selected from the ALPAKA catalog (Mullaney, 2013) with redshift between 0.1 and 0.4 and bolometric luminosity above  $10^{45.9}$  erg/s. This luminosity threshold corresponds to black hole masses above  $10^{8.2}$  solar mass, assuming an Eddington ratio typical for SDSS quasars of 0.3 (Shen et al., 2011b).

To achieve our science goal, we need to image two narrow line regions (NLRs) that are co-spatial with two stellar cores. Therefore, we observe each target with two filters, an on-band filter for the NLR(s) and an off-band filter for the continuum. To observe targets throughout our redshift range, we divide the sample into 4 redshift bins: 0.1-0.14, 0.14-0.2, 0.2-0.3, 0.3-0.4. We observe narrow line emission from H-alpha for targets with  $0.14 < z < 0.2$ , and [OIII]5007 for the rest. For each redshift interval, we observe with 2 filters chosen from the following: F547M, F621M, F689M, F763M.

We set a uniform exposure time based on a target at the fainter end of our sample (SDSSJ081755.20+312827.39). Our target is an extended source at redshift of 0.123 with a diameter of  $\sim 9$  arcsec, surface brightness in SDSS R-band of 22.6 AB mag/arcsec<sup>2</sup>, and [OIII]5007 flux density per area of  $4.3e-17$  erg/s/cm<sup>2</sup>/Angstrom/arcsec<sup>2</sup>. We will use 3-point dither for better cosmic ray subtraction. For an SNR of  $\sim 10/5$  per resolution element of 0.2 arcsec for the on- and off-band observations, the exposure times are 1200/600 seconds in the F547M/F621M filters, respectively. These calculations have taken into account post-flash for CTE loss mitigation. To avoid buffer dumps and reduce read-out time, we will use the UVIS2-C512C-SUB subarray. Our observation has  $\sim 13$  minutes of overhead, including 6.5 minutes to acquire the guide-star and 6.5 minutes to dither and change filters, and 1 minute for the final buffer dump. The total exposure time for one target is 45 minutes, or one orbit.
