95 Total Orbits Used

ABSTRACT

We propose an HST SNAP program to obtain a complete set of high-resolution near-UV (F225W) imaging from a sample of 95 broad-line AGN from the 105-month Swift/BAT survey with existing observations in at least two filters. These are among the most luminous and least obscured AGN in the nearby universe ($z < 0.1$), serving as ideal spatially resolved analogs to the X-ray-selected AGN that dominate black hole growth at cosmic noon ($z \sim 1-2$). While over 340 BAT AGN already have optical HST imaging, most lack UV data critical for breaking degeneracies between dust extinction and the intrinsic shape of the AGN spectral energy distribution (SED). Our goal is to resolve and recover the accretion disk emission the so-called "big blue bump" by obtaining a third broadband UV/optical filter. This will enable robust modeling of the nuclear SED, accretion rate, and bolometric luminosity. The proposed images, with ~ 100 parsec resolution, will also isolate nuclear star formation, the AGN point spread function, and extended UV emission from ionized gas or scattered light. We request F225W imaging for 68 AGN with two existing HST optical bands and F336W imaging for 27 AGN that already have UV coverage but only a single optical filter (e.g. 435W, 606W, 814W). Coordinated Swift/UVOT/XRT and LCOGT observations will provide quasi-simultaneous SED coverage. This legacy dataset publicly released immediately will set the benchmark for high-resolution AGN SEDs in the nearby universe and inform the design and interpretation of upcoming UV missions like the Habitable Worlds Observatory and UVEX.

OBSERVING DESCRIPTION

This is a SNAP near UV survey (NUV, $<3000 \text{ \AA}$) in the F225W filter and also 336W filter of the nearest ($z < 0.1$) and X-ray brightest AGN with black hole mass measurements from broad line H β with existing G and I-band HST imaging but no NUV imaging for 68 sources or for 27 sources a 336W image for sources with NUV imaging and only 814W imaging. These 100 pc resolution observations will resolve the power output of local AGN (point source emission in HST) and study the link of extended nuclear star formation with AGN activity. We will separate the point like AGN emission from the faint diffuse extended galaxy emission from SFR and measure its flux. These HST observations will be complemented by approved Swift/XRT and Swift/UVOT observations for broadband simultaneous SED coverage. Our observing strategy is to: 1) Obtain a short 10s sub arrayed exposure, to avoid target saturation. The median brightness is 17 mag AB in GALEX/NUV, with some brighter, and we don't know actually how bright the nucleus is compared to the host galaxy. 2) Then obtain a longer exposure of 17.5 minutes total so that we can recover and measure the extended emission. We split the longer 3 exposures into 350 seconds so the buffer dump can be put into the next exposure (need to be $>349 \text{ s}$). We use 3 separate exposure for cosmic ray elimination and to sample the PSF. We target at UVIS2 to take advantage of the better UV sensitivity. We have set the flash to max (23e) to limit CTE, since the background is so low in the UV (like 1e from the ETC).
