45 Total Orbits Used

ABSTRACT

The formation of globular clusters (GCs) is one of the most challenging problems in astrophysics: modeling and simulating GC formation has attracted a tremendous amount of effort over the past decades. However, current endeavors face a major limitation due to the strong selection bias present in current observational samples. The vast majority of existing measurements are either of massive galaxies (for which differences in models are not particularly sensitive, as their GC population is primarily accreted) or dwarf galaxies in group/cluster environments (for which highly uncertain environmental effects must be accounted for).

To remedy this observational bias, we propose snapshot observations of a sample of 45 isolated dwarf galaxies. This will dramatically expand the sample of isolated dwarf galaxies with measured GC properties, allowing for a precise characterization of the GC population of these systems that are most sensitive to GC formation physics. By measuring the intrinsic scatter of the GC mass fraction distribution, we will provide strong constraints on GC formation models: a small intrinsic scatter suggests that GCs were primarily formed very early in the Universe, whereas larger intrinsic scatter favors more continuous cluster formation models.

In addition, these observations will establish an excellent legacy for studying dwarf galaxies with HST, such as testing Ultra-Diffuse Galaxy

Proposal 18347 (STScI Edit Number: 0, Created: Thursday, September 24, 2026, 1:00:55PM Eastern Standard Time) - Overview
formation models and studying the galaxy-halo connection.

The precise measurement of the GC properties of this sample, possible with the high resolution and sensitivity of HST, will greatly improve our insight into the mystery of GC formation and evolution.

OBSERVING DESCRIPTION

Each target will be observed with ACS F814W and ACS F606W. The F814W exposures will total 700s split into two dithers, and the F606W exposures will total 800s, also split into two dithers.
