ABSTRACT

We propose a Snapshot program to measure the occurrence rate of late-time circumstellar material (CSM) interaction in short-plateau Type II supernovae (SNe II) using NUV imaging at >200 days after explosion. Short-plateau SNe II arise from red-supergiant progenitors that have lost a

significant fraction of their hydrogen envelopes prior to explosion, forming a transitional class between ordinary SNe II and stripped-envelope SNe IIb. Whether this enhanced mass loss produces dense circumstellar environments detectable at late times remains an open question. A systematic NUV survey can answer it: at late epochs, radioactive heating has faded and interaction-powered emission is dominated by UV lines of Mg II and Fe II, making the NUV the most sensitive diagnostic of ongoing ejecta-CSM interaction regardless of CSM composition. Recent HST UV studies of SN 2023ixf have demonstrated that such interaction can dominate the UV for hundreds of days, and a statistical survey of stripped-envelope SNe (SNAP-16657) found UV detections attributable to CSM in 6/91 observed SNe. No dedicated HST survey has yet targeted the short-plateau SN II subclass specifically. This NUV Snapshot program targets a systematically selected sample of 181 short-plateau SNe II from the public Zwicky Transient Facility Bright Transient Survey, requiring only a single sub-orbit visit per target. NUV imaging will determine whether partial envelope stripping is coupled to enhanced pre-supernova mass loss, constrain the prevalence and properties of CSM around this subclass, and offer novel tests of both single-star and binary-star models for the diversity of hydrogen-rich SN progenitors.

OBSERVING DESCRIPTION

WFC3/UVIS Snapshot imaging of 181 short-plateau and fast-declining Type II supernovae selected from ZTF. Each target receives a single visit within one orbit, with all exposures dithered over the two points of a WFC3-UVIS-DITHER-LINE pattern (0.145 arcsec spacing) for cosmic-ray rejection and sub-pixel sampling. Exposures use the UVIS2-C1K1C-CTE subarray, which places the target close to the readout amplifier and so minimises CTE losses for these faint sources; the 14 nearest targets described below instead use the full UVIS field, whose wider field of view is needed for astrometric registration and host context at those distances. F275W: 550 s per dither point (1100 s total) with 20 e- post-flash, identical for every target; this is the primary interaction diagnostic. F555W: 200 s per point (400 s total) with 12 e- post-flash for the majority of the sample, which provides the contemporaneous optical reference and UV-optical color needed to separate genuinely blue SN-site emission from host light (i.e. compact star formation regions). For the 14 nearest targets (z below 0.011, D below 45 Mpc), where a search for a surviving binary companion is sensitive, F555W is deepened to 550 s per point (1100 s total) with 8 e- post-flash, reaching V of about 27.3 and hence M_V of -4.4 to -6 at those distances. Post-flash levels are set to keep the total background above roughly 20 e- per frame for CTE mitigation. All targets are 302-3243 days past peak brightness during Cycle 34, so no timing constraints, orientation constraints or other special requirements are needed, and any target may be executed at any time in the cycle.

Diagnostic Status: No Diagnostics

Scientific Instruments: WFC3/UVIS

Special Requirements: (none)

Comments: Duplication note: prior late-time F275W imaging in our GO-16657. This visit provides a second UV epoch to test variability of the candidate CSM interaction; approved science case targets the late-time UV detection fraction of this subclass.

Scientific Instruments: WFC3/UVIS

Special Requirements: (none)

Comments: Duplication note: prior UV imaging in GO-17181 at an earlier phase. This visit probes the late-time (>280 d) CSM-interaction epoch; the earlier data provide a first epoch for variability comparison rather than a duplication.
