ABSTRACT

We propose CLUTCH: The COSMOS Legacy UV-Optical Treasury Campaign with Hubble. CLUTCH is a Multi-Cycle Treasury program to image 0.5deg^2, overlapping the areas observed by COSMOS-Web and COSMOS-3D. CLUTCH will observe the rest-frame UV to optical emission for galaxies from z<7.5 utilizing WFC3-UVIS F225+F275W, ACS F435W+F606W+F814W, and WFC3-IR F098M, all of which are inaccessible by JWST. While JWST is a fantastic resource for obtaining rest-frame UV emission out to the very highest redshifts, obtaining equivalent information below z~3, encompassing over three-quarters of the universe's history, requires Hubble. JWST also relies on deep Hubble observations for redshift estimates of sources near the end of the Epoch of Reionization (5.5<z<7.5). Though extragalactic surveys of other fields have obtained deep Hubble UV observations, the critical wide-area level of the `wedding cake' is missing. CLUTCH will cover an area 4.2x larger than UVCANDELS and 3.4x larger than other UV surveys combined. This layer is essential for probing environmental effects on large scales, obtaining robust samples in several redshift and other physical property (e.g., stellar mass, morphology) bins, mitigating cosmic variance, and studying rare sources.

With CLUTCH, we will be able to:
1) Investigate the history of stellar mass assembly and the impact of local environment on galaxies' evolutionary pathways,
2) Study dust attenuation in low-z galaxies and constrain the 2175 A absorption feature,
3) Map large scale structure out to z~7.5 and use LAEs to trace reionization bubbles using vastly improved photozs, and
4) Create a large training sample for the latest generation weak lensing surveys.

OBSERVING DESCRIPTION

CLUTCH is a 6-filter survey, covering ~0.5 deg^2 with WFC3-UVIS F225W+F275W, ACS F435W+F606W+F814W, and WFC3-IR F098M.

Our mapping strategy has four prime exposures in WFC3 per orbit, and four exposures for ACS as coordinated parallels. In each orbit, the 4-point dither pattern consists of a large 2-point primary dither (~120") parallel to the PA, along with a smaller 2-point secondary dither (~8",2") orthogonal to the PA, resulting in a total of 3 moves during the orbit after the first exposure is obtained at (0,0). Exposures from different orbits are then stitched together such that the full mosaic is covered at ~1/2 orbit depth in WFC3 and ~1 orbit depth in ACS. Since the FOV for WFC3/UVIS is slightly larger than WFC3/IR, a small fraction of the UVIS mosaics will have deeper coverage while maintaining uniform coverage in ACS. We request observations at epochs with lower zodiacal background to maximize the survey depth (corresponding to ORIENT ~290), and for WFC3/IR we request low sky background since the F098M filter is especially susceptible to geocoronal line emission. We have calculated sub-pixel dithering to

provide 1/2-pixel subsampling for the prime and parallel exposures, following approaches described in ACS ISR 2023-04 (while recognizing that our necessary large dithers will result in some pixel phase wrapping across the detector, though this is generally mitigated by overlapping exposures from adjacent visits). For the WFC3/IR readout pattern we use SPARS100 with NSAMP=6 (patterns with shorter sample sequences and more samples lead to a data rate that's too high and would result in WFC3 buffer dumps midway through the orbit, causing remaining observations to spill over into a subsequent orbit), therefore SPARS100 with NSAMP=6 is our optimal readout strategy for WFC3/IR.

Given our tiling/exposure strategy and the required area coverage, there are discrete choices for filter depth. We request here the min. depth per pointing that will provide the necessary number of exposures and accomplish our science goals resulting in the following 5sigma point source depths (all in AB): F225W: 25.7, F275W: 26.1, F435W: 27.8, F606W: 28.2, F814W: 27.8, and F098M: 26.6.
